Here is the introduction. Lorem ipsum bla bla bla Hoe hoger de sem dis is, hoe gevarieerder de paden van mensen zullen path length, variance and sematic distance

2 BACKGROUND

Here is the background. Lorem ipsum bla bla bla

3 SEMANTIC DISTANCE

4 EXPERIMENTAL SETUP

The experimental setup consists of two parts.

In the first part, we plot the average distance between two articles against the variance of the distances. We take the set of start, goal tuples from the dataset (s, g), and for each tuple we "COMPUTE???" all distances between articles in the path from s to g . Note that we do not consider all possible paths from s to g , but only the path that was taken by the user in the dataset. We then compute the average and variance of these distances, and plot them against each other. We do this for all start goal tuples in the dataset.

The second part of the experiment is inspired by Fitts' law, where we compare the variance in distance between two articles with the semantic distance. The semantic distance is computed by the method described in section 3. More specifically, we take all pairs of articles (a_1, a_2) in the dataset, calculate the variance of the distance for each pair, and compute the semantic distance between them. We then make a 2 dimensional plot with the semantic distance on the x-axis and the variance over distance on the y-axis. On the y-axis we use variance of distance, since
